

# Package ‘monmlp’

August 29, 2013

**Type** Package

**Title** Monotone multi-layer perceptron neural network

**Version** 1.1.2

**Author** Alex J. Cannon

**Maintainer** Alex J. Cannon <acannon@eos.ubc.ca>

**Description** Multi-layer perceptron neural network with partial monotonicity constraints

**License** GPL-2

**LazyLoad** yes

**Repository** CRAN

**Date/Publication** 2012-09-27 17:29:56

**NeedsCompilation** no

monmlp-package

*Monotone multi-layer perceptron neural network***Description**

The monmlp package implements the monotone multi-layer perceptron neural network (MON-MLP) model following Zhang and Zhang (1999). The main feature is the monotone constraint, which guarantees monotonically increasing behaviour of model outputs with respect to specified covariates. The package also features model architectures with one or two hidden layers, analytical calculation of the gradient via backpropagation, optimization using the `nlm` routine, and optional use of early stopping in conjunction with bootstrap aggregation to control overfitting. The model reduces to a standard multi-layer perceptron neural network if the monotone constraint is not invoked.

MONMLP models are fit using the `monmlp.fit` function. Predictions from a fitted model are made using the `monmlp.predict` function. The `gam.style` function can be used to investigate fitted predictor/predictand relationships. Most other functions are used internally and should not need to be called directly by the user.

**Details**

Package:	monmlp
Type:	Package
License:	GPL-2
LazyLoad:	yes

gam.style

*GAM-style effects plots for interpreting MONMLP models***Description**

GAM-style effects plots provide a graphical means of interpreting fitted MONMLP predictor/predictor relationships. From Plate et al. (2000): The effect of the  $i$ th input variable at a particular input point  $\Delta x_i$  is the change in  $f$  resulting from changing  $x_i$  to  $x_i + \Delta x_i$  from  $b_i$  (the baseline value [...]) while keeping the other inputs constant. The effects are plotted as short line segments, centered at  $(x_i, \Delta x_i)$ , where the slope of the segment is given by the partial derivative. Variables that strongly influence the function value have a large total vertical range of effects. Functions without interactions appear as possibly broken straight lines (linear functions) or curves (nonlinear functions). Interactions show up as vertical spread at a particular horizontal location, that is, a vertical scattering of segments. Interactions are present when the effect of a variable depends on the values of other variables.

**Usage**

```
gam.style(x, weights, column, baseline = mean(x[,column]),
          epsilon = 1e-5, seg.len = 0.02, seg.cols = "black",
          plot = TRUE, return.results = FALSE, ...)
```

**Arguments**

<code>x</code>	matrix with number of rows equal to the number of samples and number of columns equal to the number of predictor variables.
<code>weights</code>	list returned by <code>monmlp.fit</code> .
<code>column</code>	column of <code>x</code> for which effects plots should be returned.
<code>baseline</code>	value of <code>x[, column]</code> to be used as the baseline for calculation of predictor effects; defaults to <code>mean(x[, column])</code> .
<code>epsilon</code>	step-size used in the finite difference calculation of the partial derivatives.
<code>seg.len</code>	length of effects line segments expressed as a fraction of the range of <code>x[, column]</code> .
<code>seg.cols</code>	colors of effects line segments.
<code>plot</code>	if TRUE (the default) then an effects plots for each predictand variable is produced.
<code>return.results</code>	if TRUE then values of effects and partial derivatives for each predictand variable are returned.
<code>...</code>	further arguments to be passed to <code>plot</code> .

**Value**

A list with elements:

<code>effects</code>	a matrix of predictor effects.
<code>partials</code>	a matrix of predictor partial derivatives.

## Examples

```
set.seed(1)
x <- matrix(runif(350*6), ncol=6)
y <- as.matrix(5*sin(10*x[,1]*x[,2]) + 20*(x[,3]-0.5)^2 -
              10*x[,4] + 20*x[,5]*x[,6])

w <- monmlp.fit(x = x, y = y, hidden1 = 4, n.trials = 1)

for (i in 1:ncol(x)) gam.style(x, weights = w, column = i)
```

---

linear

*Identity function*

---

## Description

Computes a trivial identity function. Used as the hidden layer transfer function for linear MONMLP models.

## Usage

```
linear(x)
```

## Arguments

**x**                      numeric vector.

## See Also

monmlp.cost	<i>Least squares cost function for MONMLP fitting</i>
-------------	---

---

**Description**

MONMLP mean squared error cost function with analytical calculation of its gradient via back-propagation.

**Usage**

```
monmlp.cost(weights, x, y, hidden1, hidden2, Th, To, Th.prime,
             To.prime, monotone = NULL)
```

**Arguments**

weights	vector of weights.
x	covariate matrix with number of rows equal to the number of samples and number of columns equal to the number of covariates.
y	predictand matrix with number of rows equal to the number of samples and number of columns equal to the number of predictands.
hidden1	number of hidden nodes in the first hidden layer.
hidden2	number of hidden nodes in the second hidden layer.
Th	hidden layer transfer function.
To	output layer transfer function.
Th.prime	derivative of the hidden layer transfer function.
To.prime	derivative of the output layer transfer function.
monotone	column indices of covariates for which the monotonicity constraint should hold.

**Value**

numeric value giving the mean squared error with associated gradient attached as an attribute.

**See Also**

[monmlp.cost](#), [monmlp.nlm](#), [monmlp.fit](#)

---

monmlp.fit	<i>Fit a MONMLP model or an ensemble of MONMLP models</i>
------------	---

---

**Description**

Fit a MONMLP model or an ensemble of MONMLP models using the [nlm](#) optimization routine. Optional stopped training and bootstrap aggregation (bagging) can be used to help avoid overfitting. If invoked, the monotone argument enforces increasing behaviour between specified columns of *x* and model outputs.

Note: *x* and *y* are automatically standardized prior to fitting and predictions are automatically rescaled by [monmlp.predict](#). This behaviour can be suppressed for *y* by the `scale.y` argument.

**Usage**

```
monmlp.fit(x, y, hidden1, hidden2 = 0, iter.max = 5000,
           n.trials = 1, n.ensemble = 1, bag = FALSE,
           cases.specified = NULL, iter.stopped = NULL,
           scale.y = TRUE, Th = tansig, To = linear,
           Th.prime = tansig.prime, To.prime = linear.prime,
           monotone = NULL, init.weights = c(-0.5, 0.5),
           max.exceptions = 10, silent = FALSE, ...)
```

**Arguments**

<i>x</i>	covariate matrix with number of rows equal to the number of samples and number of columns equal to the number of covariates.
<i>y</i>	predictand matrix with number of rows equal to the number of samples and number of columns equal to the number of predictands.
<i>hidden1</i>	number of hidden nodes in the first hidden layer.
<i>hidden2</i>	number of hidden nodes in the second hidden layer.
<i>iter.max</i>	maximum number of iterations of the <a href="#">nlm</a> optimization algorithm.
<i>n.trials</i>	number of repeated trials used to avoid local minima.
<i>n.ensemble</i>	number of ensemble members to fit.
<i>bag</i>	logical variable indicating whether or not bootstrap aggregation (bagging) should be used.
<i>cases.specified</i>	if <i>bag</i> = TRUE, a list that specifies the bootstrapped cases to be used in each ensemble member.

<code>iter.stopped</code>	if <code>bag = TRUE</code> , specifies the number of stopped training iterations between calculation of the cost function on the out-of-bootstrap cases.
<code>scale.y</code>	logical determining if columns of the predictand matrix should be scaled to zero mean and unit variance prior to fitting. Set this to <code>FALSE</code> if using an output layer transfer function that limits the range of predictions.
<code>Th</code>	hidden layer transfer function.
<code>To</code>	output layer transfer function.
<code>Th.prime</code>	derivative of the hidden layer transfer function.
<code>To.prime</code>	derivative of the output layer transfer function.
<code>monotone</code>	column indices of covariates for which the monotonicity constraint should hold.
<code>init.weights</code>	either a vector giving the minimum and maximum allowable values of the random weights or an initial weight vector.
<code>max.exceptions</code>	maximum number of exceptions of the <code>nlm</code> routine before fitting is terminated with an error.
<code>silent</code>	logical determining if diagnostic messages should be suppressed.
<code>...</code>	additional parameters passed to the <code>nlm</code> optimization routine.

### Value

list containing fitted weight matrices with attributes including called values of `x`, `y`, `Th`, `To`, `Th.prime`, `To.prime`, `monotone`, `bag`, `iter.max`, and `iter.stopped`, along with values of covariate/predictand column means and standard deviations (`x.center`, `x.scale`, `y.center`, `y.scale`), out-of-bootstrap cases `oob`, predicted values `y.pred`, and, if stopped training is switched on, the iteration `iter.best` and value of the cost function `cost.best` that minimized the out-of-bootstrap validation error.

### See Also

### Examples

```
set.seed(123)
x <- as.matrix(seq(-10, 10, length = 100))
y <- logistic(x) + rnorm(100, sd = 0.2)

plot(x, y)
lines(x, logistic(x), lwd = 10, col = "gray")

## MLP w/ 2 hidden nodes
w.mlp <- monmlp.fit(x = x, y = y, hidden1 = 2)
lines(x, attr(w.mlp, "y.pred"), col = "red", lwd = 3)

## MLP w/ 2 hidden nodes and stopped training
w.stp <- monmlp.fit(x = x, y = y, hidden1 = 2, bag = TRUE,
  iter.stopped = 50)
lines(x, attr(w.stp, "y.pred"), col = "orange", lwd = 3)
```

```
## MONMLP w/ 2 hidden nodes
w.mon <- monmlp.fit(x = x, y = y, hidden1 = 2, monotone = 1)
lines(x, attr(w.mon, "y.pred"), col = "blue", lwd = 3)
```

---

monmlp.initialize	<i>Initialize a MONMLP weight vector</i>
-------------------	--

---

## Description

Uniform random initialization of the weight vector used during fitting of a MONMLP model.

## Usage

```
monmlp.initialize(x, y, hidden1, hidden2, init.weights)
```

## Arguments

x	covariate matrix with number of rows equal to the number of samples and number of columns equal to the number of covariates.
y	predictand column matrix with number of rows equal to the number of samples.
hidden1	number of hidden nodes in the first hidden layer.
hidden2	number of hidden nodes in the second hidden layer.
init.weights	vector giving the minimum and maximum allowable values of the random weights.

## See Also

[monmlp.reshape](#)

---

monmlp.nlm	<i>Fit MONMLP model via nlm optimization function</i>
------------	---

---

## Description

Helper function used to fit a MONMLP model via the [nlm](#) routine.

## Usage

```
monmlp.nlm(x, y, hidden1, hidden2 = 0, iter.max = 5000,
           n.trials = 1, Th = tansig, To = linear,
           Th.prime = tansig.prime, To.prime = linear.prime,
           monotone = NULL, init.weights = c(-0.5, 0.5),
           max.exceptions = 10, silent = FALSE, ...)
```

**Arguments**

<code>x</code>	covariate matrix with number of rows equal to the number of samples and number of columns equal to the number of covariates.
<code>y</code>	predictand matrix with number of rows equal to the number of samples and number of columns equal to the number of predictands.
<code>hidden1</code>	number of hidden nodes in the first hidden layer.
<code>hidden2</code>	number of hidden nodes in the second hidden layer.
<code>iter.max</code>	maximum number of iterations of the <a href="#">nlm</a> optimization algorithm.
<code>n.trials</code>	number of repeated trials used to avoid local minima.
<code>Th</code>	hidden layer transfer function.
<code>To</code>	output layer transfer function.
<code>Th.prime</code>	derivative of the hidden layer transfer function.
<code>To.prime</code>	derivative of the output layer transfer function.
<code>monotone</code>	column indices of covariates for which the monotonicity constraint should hold.
<code>init.weights</code>	either a vector giving the minimum and maximum allowable values of the random weights or an initial weight vector.
<code>max.exceptions</code>	maximum number of exceptions of the <a href="#">nlm</a> routine before fitting is terminated with an error.
<code>silent</code>	logical determining if diagnostic messages should be suppressed.
<code>...</code>	additional parameters passed to the <a href="#">nlm</a> optimization routine.

**Value**

a list containing elements	
<code>weights</code>	final weight vector
<code>cost</code>	final value of the cost function
<code>code</code>	termination code from <a href="#">nlm</a>

**See Also**

[monmlp.fit](#)

---

monmlp.predict	<i>Make predictions from a fitted MONMLP model</i>
----------------	--

---

**Description**

Make predictions from a fitted MONMLP model or ensemble of MONMLP models.

**Usage**

```
monmlp.predict(x, weights)
```

**Arguments**

x	covariate matrix with number of rows equal to the number of samples and number of columns equal to the number of covariates.
weights	list containing MONMLP weight matrices and other parameters from <a href="#">monmlp.fit</a> .

**Value**

a matrix with number of rows equal to the number of samples and number of columns equal to the number of predictand variables. If weights is from an ensemble of models, the matrix is the ensemble mean and the attribute ensemble contains a list with predictions for each ensemble member.

**See Also**

[monmlp.fit](#)

**Examples**

```
set.seed(123)
x <- as.matrix(seq(-10, 10, length = 100))
y <- logistic(x) + rnorm(100, sd = 0.2)

plot(x, y)
lines(x, logistic(x), lwd = 10, col = "gray")

## Ensemble of MONMLP models w/ 3 hidden nodes
w.mon <- monmlp.fit(x = x, y = y, hidden1 = 3, monotone = 1,
                   n.ensemble = 15, bag = TRUE)
p.mon <- monmlp.predict(x = x, weights = w.mon)

## Plot predictions from ensemble members
for(i in 1:15)
  lines(x, attr(p.mon, "ensemble")[[i]], col = "cyan")

## Plot ensemble mean
lines(x, p.mon, col = "blue", lwd = 3)
```

---

monmlp.reshape	<i>Reshape a MONMLP weight vector</i>
----------------	---------------------------------------

---

**Description**

Reshapes a weight vector used during fitting of a MONMLP model into the appropriate weight matrices.

**Usage**

```
monmlp.reshape(x, y, weights, hidden1, hidden2)
```

**Arguments**

x	covariate matrix with number of rows equal to the number of samples and number of columns equal to the number of covariates.
y	predictand matrix with number of rows equal to the number of samples and number of columns equal to the number of predictands.
weights	weight vector of length returned by <a href="#">monmlp.initialize</a> .
hidden1	number of hidden nodes in the first hidden layer.
hidden2	number of hidden nodes in the second hidden layer.

**See Also**

---

tansig	<i>Hyperbolic tangent sigmoid function</i>
--------	--

---

**Description**

Computes the hyperbolic tangent sigmoid function. Used as a hidden layer transfer function for nonlinear MONMLP models.

**Usage**

```
tansig(x)
```

**Arguments**

x	numeric vector.
---	-----------------

**See Also**

[tansig.prime](#)

---

`tansig.prime`*Derivative of the hyperbolic tangent function*

---

**Description**

Derivative of the hyperbolic tangent function.

**Usage**

```
tansig.prime(x)
```

**Arguments**

`x`                      numeric vector.
